## Adenosine Newborn Use Only

| Alert             | Adenosine is not a maintenance antiarrhythmic agent. Infants with SVT associated with serious  |  |
|-------------------|--|--|
|                   | cardiovascular compromise such as severe hypotension and decompensated heart failure should be   |  |
| Indiantian        | converted with synchronised electrical cardioversion rather than adenosine.  |  |
| Indication        | Supraventricular tachycardia. [1, 2]   |  |
| Action            | Endogenous purine analogue with rapid onset antiarrhythmic action resulting in transient AV nodal block.<br>It has a short half-life (1–10 seconds). [3] |  |
| Drug Type         | Antiarrhythmic   |  |
| Trade Name        | Adenocor, Adenosine Mylan injection  |  |
| Presentation      | 6 mg/2 mL injection  |  |
| Dose              | 1 <sup>st</sup> dose: 100 microgram/kg/dose. If no response within 2 minutes,* administer  |  |
| 5000              | 2 <sup>nd</sup> dose: 200 microgram/kg/dose. If no response within 2 minutes,* administer  |  |
|                   | 3 <sup>rd</sup> dose: 300 microgram/kg/dose.   |  |
|                   |  |  |
|                   | *Often, poor response is due to incorrect method of administration. Please ensure it is administered by  |  |
|                   | rapid IV push through a proximal vein followed immediately by flush.   |  |
|                   | If further doses are required, to discuss with cardiology team.  |  |
| Dose adjustment   | Not applicable.  |  |
| Maximum dose      | The first dose should not exceed 6 mg and the second dose 12 mg. [1] If multiple doses are required  |  |
|                   | within 24 hours, consult cardiologist to discuss further management.   |  |
| Route             | Intravenous  |  |
|                   | Successful intraosseous administration has been reported.  |  |
| Preparation       | Draw up 1 mL (3000 microgram) and add 9 mL sodium chloride 0.9% to make a final volume of 10mL with  |  |
|                   | a concentration of 300 microgram/mL.   |  |
| Administration    | Intravenous as a rapid bolus through proximal vein followed immediately by 3-5 mL of sodium chloride   |  |
|                   | 0.9% flush. Use a three-way stopcock and connect 2 syringes, one with adenosine and the other with   |  |
|                   | sodium chloride 0.9% to ensure rapid bolus. Do not use filter. Use of filter may slow down infusion.   |  |
| Monitoring        | Adenosine should be used only where cardiac monitoring and cardiorespiratory resuscitation equipment   |  |
| 0                 | is available for immediate use if necessary.   |  |
| Contraindications | Known hypersensitivity to adenosine; sick sinus syndrome, second or third degree AV block (except in   |  |
|                   | patients with a functioning artificial pacemaker); long QT syndrome; severe hypotension; decompensated   |  |
|                   | states of heart failure.   |  |
|                   | Atrial fibrillation or flutter but can be useful to unmask atrial flutter.   |  |
| Precautions       | Patients who develop high level atrioventricular block or returned to sinus rhythm at a particular dose  |  |
|                   | should not be given further dosage increments.   |  |
|                   | Solution must be clear at time of administration.  |  |
|                   | Bronchoconstriction (Exacerbation was reported in adults) <sup>7</sup>   |  |
| Drug Interactions | Dipyridamole was shown to produce a 4-fold increase in adenosine activity. Dipyridamole should be  |  |
|                   | discontinued 24 hours beforehand or the dose of adenosine should be significantly reduced.   |  |
|                   | Adenosine may interact with drugs that tend to impair cardiac conduction. Aminophylline, theophylline  |  |
|                   | and caffeine are competitive adenosine antagonists and should be avoided for 24 hours prior to the   |  |
|                   | administration of adenosine. Additionally their concomitant use may result in increased risk of seizures. <sup>6</sup>                                   |  |
|                   | Adenosine has been effectively administered in the presence of other cardioactive drugs, such as digitalis,  |  |
|                   | quinidine, beta-adrenergic blocking agents, calcium channel blocking agents and angiotensin converting   |  |
|                   | enzyme inhibitors, without any change in the adverse reaction profile.   |  |
| Adverse Reactions | Very rare reactions (mostly reported in adults): atrial fibrillation; ventricular fibrillation and torsades de   |  |
|                   | pointes; severe bradycardia not corrected by atropine and possibly requiring temporary pacing.   |  |
|                   | Hypotension has been reported.   |  |
|                   | Bronchospasm. <sup>6</sup>   |  |
| Compatibility     | Fluids: Glucose 5%, sodium chloride 0.9%   |  |
|                   | Y-site: No information.  |  |
| Incompatibility   | Fluids and Y-site: No information.   |  |
| Stability         | Discard remainder after use.   |  |

| Storage          | Store below 25°C. Protect from light. Do not refrigerate –crystallisation may occur.  |  |  |
|------------------|---|--|--|
| Excipients       | Sodium chloride, water for injections.  |  |  |
| Special Comments | Treatment of any prolonged adverse effects should be individualised and directed to specific symptoms.  |  |  |
| Evidence         | <ul> <li>ARC 2010 treatment recommendations for supraventricular tachycardia: If haemodynamically stable</li> <li>(adequate perfusion and blood pressure), initial treatment of SVT for infants and young children should be</li> <li>application to the face of a plastic bag filled with iced-water.[LOE IV; GOR B]. If drug therapy required,</li> <li>adenosine is the drug of choice. It has a very short half-life and must be given as a rapid intravenous or</li> <li>intraosseous bolus and flushed with 0.9% sodium chloride into the circulation. A dose in the range of 0.1</li> <li>to 0.3 mg/kg converts most cases to sinus rhythm [LOE IV; GOR B]. The initial recommended dose is 0.1</li> <li>mg/kg but if this is ineffective, the dose should be increased to 0.2 mg/kg. The first dose should not</li> <li>exceed 6 mg and the second dose 12 mg. [1]</li> <li>Pharmacokinetics: Adenosine is an endogenous purine analogue with rapid onset and the short half-life</li> <li>(1–10 sec). Adenosine exerts its antiarrhythmic actions by activation of A1 adenosine receptors located in</li> <li>the sinoatrial and atrioventricular nodes, as well as in activated ventricular myocardium.[3]</li> <li>Safety: A few cases of adenosine-induced tachyarrhythmia e.g. torsades de pointes, have occurred.[1]</li> </ul>   |  |  |
